STUDENT OUTLINE

Lesson 19 – Single Dimension Arrays

INTRODUCTION: Programs often need a way to work with large amounts of data without declaring thousands of scalar variables. In this lesson we explain the terms *data structure* and *algorithm*, and then introduce you to a very important data structure, the *array*. With each new data structure comes the complementary algorithms to manipulate the data it stores. This combination of data structures and algorithms provide the powerful tools needed to solve computer science problems.

The key topics for this lesson are:

A. Data Structures and Algorithms
B. Example of an Array
C. Array Declarations and Memory Allocation
D. Applications of Arrays
E. Arrays as Parameters
F. Arrays and Algorithms

VOCABULARY:

DATA STRUCTURE	ALGORITHM
TRAVERSAL	ARRAY
SEQUENTIAL	RANDOM ACCESS
INDEX	`final`

DISCUSSION:

A. Data Structures and Algorithms

1. A scalar type is a simple data type that holds one value at a time. The data types **`int`**, **`double`**, **`char`**, and **`boolean`** are important and useful, but limited.

2. A data structure is a collection of scalar data types that are all referenced or accessed through one identifier.

3. Data structures can be created to store information about any real-world situation:
   a. Your high school transcript is a collection of grades.
   b. The English paper you wrote on a word processor is stored as a collection of characters, punctuation, and formatting codes.
   c. Your name, address, and phone number can be stored as a collection of strings.

4. After defining a data structure, algorithms will be needed to solve the specific problems associated with such a data structure.

5. One example of a data structure is an array. An array will store a list of values.
6. An algorithm is a sequence of programmed steps that solves a specific problem.

7. The fundamental algorithms that apply to an array data structure are: insertion, deletion, traversal, searching, and sorting.

B. Example of an Array

1. The following program will introduce you to some of the syntax and usage of the *array* class in Java:

Program 19-1

```
public class ArrayExample
{
  public static void main (String[] args)
  {
    int[] A = new int[6];  //  an array of 6 integers
    int loop;

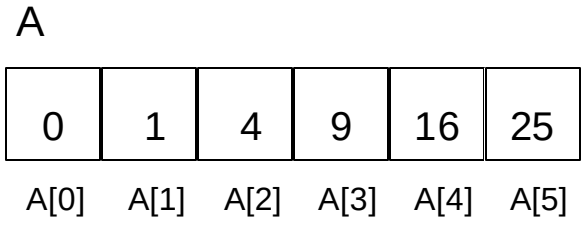
    for (loop = 0; loop < 6; loop++)
      A[loop] = loop * loop;
    System.out.println("The contents of array A are:");
    System.out.println();
    for (loop = 0; loop < 6; loop++)
      System.out.print("  " + A[loop]);
    System.out.println();
  }
}
```

Run output:

```
The contents of array A are:

  0  1  4  9  16  25
```

2. An array is a linear data structure composed of adjacent memory locations, or "cells", each holding values of the same type.



3. The variable A is an array, a group of 6 related scalar values. There are six locations in this array referenced by index positions 0 to 5. Note that indexes

always start at zero, and count up by one's until the last slot of the array. If there are N slots in an array, the indexes will be 0 through N-1.

4. The variable `loop` is used in a **`for`** loop to reference index positions 0 through 5. In this program the square of each index position is stored in the memory location occupied by each cell of the array. The syntax for accessing a memory location of an array requires the use of square brackets `[]`.

5. The square brackets `[]` are collectively an operator in Java. They are similar to the parentheses as they have the highest level of precedence compared to all other operators.

6. The index operator performs automatic bounds checking. Bounds checking makes sure that the index is within the range for the array being referenced. Whenever a reference to an array element is made, the index must be greater than or equal to zero and less than the size of the array. If the index is not valid, the exception `ArrayIndexOutOfBoundsException` is thrown.

C. Array Declarations and Memory Allocation

1. Array declarations look like this:

```
type[] arrayName;
```

This tells the compiler that `arrayName` will be used as the name of an array containing ***`type`***. However, the actual array is not constructed by this declaration. Often an array is declared and constructed in one statement like this:

```
type[] arrayName = new type[length];
```

This tells the compiler that `arrayName` will be used as the name of an array containing ***`type`***, and constructs an array object containing `length` number of slots.

2. An array is an object, and like any other object in Java is constructed out of main storage as the program is running. The array constructor uses different syntax than most object constructors; ***`type`***`[length]` names the type of data in each slot and the number of slots. For example:

```
int[] list = new int[6];
double[] data = new double[1000];
Student[] school = new Student[1250];
```

Once an array has been constructed, the number of slots it has does not change.

3. The size of an array can be defined by using a **`final`** value, which means that you cannot change it or derive from it later.

```
final int MAX = 200;
int[] numb = new int[MAX];
```

4. When an array is declared, enough memory is allocated to set up the full size of the array. For example, the array of **`int`** as described above,

```
int[] list = new int[6]
```

will require 24 bytes of memory (4 bytes per cell).

D. Application of Arrays

1. Suppose we have a text file *votes.txt* of integer data containing all the votes cast in an election. This election happened to have three candidates and the values in the integer file are 1, 2, or 3, each corresponding to one of the three candidates.

Program 19-2

```
import chn.util.*;

public class Votes
{
  public static void main (String[] args)
  {
    FileInput inFile = new FileInput("votes.txt");

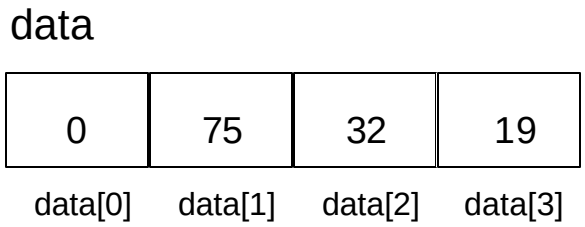
    int vote, total = 0, loop;

    // sized to 4 boxes, initialized to 0's
    int[] data = new int[4];

    vote = inFile.readInt();
    while (inFile.hasMoreTokens())
    {
      data[vote]++;
      total++;
      vote = inFile.readInt();
    }
    System.out.println("Total # of votes = " + total);
    for (loop = 1; loop <= 3; loop++)
      System.out.println("Votes for #" + loop +
                         " = " + data[loop]);

  }
}
```

a. The array `data` consists of four cells, each holding an integer value. The first cell, `data[0]`, is allocated but not used in this problem. After processing the entire file, the variable `data[n]` contains the number of votes for candidate n. We could have stored the information for candidate 1 in position 0, candidate 2 in position 1, and so forth, but the code is easier to follow if we can use a direct correspondence.



b. The value of `vote` is used to increment the appropriate cell of the array by +1.

2. A second example counts the occurrence of each alphabet letter in a text file.

Program 19-3

```
import chn.util.*;

public class CountLetters
{
  public static void main (String[] args)
  {
    FileInput inFile = new FileInput("sample.txt");

    int[] letters = new int[27]; // use positions 1..26
                                 //  to count letters
    int total = 0;
    char ch;

    while (inFile.hasMoreLines())
    {
      String line = inFile.readLine().toLowerCase();
      for(int index = 0; index < line.length(); index++)
      {
        ch = line.charAt(index);
        // line.charAt is from chn.util. It extracts the entry.

        if ('a' <= ch && ch <= 'z')  // if we have a letter...
        {
          letters[ch - 96]++;  // if ch == 'a', 97-96 = 1, etc.
          total++;
        }
      }
    }
```

```
    System.out.println("Count letters");
    System.out.println();
    ch = 'a';
    for (int loop = 1; loop <= 26; loop++)
    {
      System.out.println(ch + " : " + letters[loop]);
      ch++;
    }
    System.out.println();
    System.out.println("Total letters = " + total);
  }
}
```

a. Each line in the text file is read in and then each character in the line is copied into `ch`. If `ch` is an uppercase letter, it is converted to its lowercase counterpart.
b. If the character is a letter, the ASCII value of the letter is adjusted to fit the range from 1-26. For example, if `ch == 'a'`, the program solves `97 - 96 = 1`. Then the appropriate cell of the array is incremented by one.
c. Again, position 0 in the array is not used to make the data processing easier.

E. Arrays as Parameters

See ArrayOps.java, ***Example Program - Arrays as Parameters.***

1. The program *ArrayOps.java*, provides examples of passing arrays as parameters. Notice that the **`final`** integer constant `MAX = 6` is used to size the array in this program.

2. The `main` method declares an array named `data`. The array is initialized with the values 0...5 inside the `main` method.

3. The parameters of the `squareList` and `printList` methods are references to an array object. Any local reference to array `list` inside the `squareList` or `printList` methods is an alias for the array `data` inside of the `main` method. Notice that after the call of `squareList`, the values stored in array `data` in the `main` method have been permanently changed.

4. When the `rotateList` method is called, the copy method of the `ArrayOps` class is invoked and the local array `listCopy` is created as a copy of the array `data` in the `main` method.

5. The `rotateList` method rotates the values one cell to the right, with the last value moved to the front of the list. A call to `printList` is made inside the

`rotateList` method just before leaving the method. After returning to the `main` method, notice that the array `data` is unchanged.

F. Arrays and Algorithms

In the following list we introduce five important algorithms that are quite common in programs that analyze data in arrays. You will meet these again in later lessons and labs.

1. Insertion is a standard problem that must be solved for all data structures. Suppose an array had 10 values and an 11th value was to be added. We are assuming the array can store at least 11 values.

   a. If we could place the new value at the end, there would be no problem.
   b. But if the new value must be inserted at the beginning of the list in position 0, the other 10 values must be moved one cell down the list.

2. Deletion of a value creates an empty cell that probably must be dealt with. The most likely solution after deleting a value, is to move all values that are to the right of the empty spot one cell to the left.

3. A traversal of an array consists of visiting every cell location, probably in order. The visit could involve printing out the array, initializing the array, finding the largest or smallest value in the array, etc.

4. Sorting an array means to organize values in either ascending or descending order. These algorithms will be covered in depth in future lessons.

5. Searching an array means to find a specific value in the array. There are several standard algorithms for searching an array. These will be covered in future lessons.

SUMMARY/ REVIEW: Arrays are extremely useful data structures and you will have many opportunities (lots of labs!) to program with them. After spending a few days working with single dimension arrays, we will move on to multi-dimensional arrays.

ASSIGNMENT: Lab Exercise L.A.19.1, *Statistics*
Lab Exercise L.A.19.2, *Compact*

LAB EXERCISE

Statistics

Background:

1. Your instructor will provide you with a text file, (*numbers.txt*), containing a large (N <= 1000) number of integers. The integers range in value from 0 to 100. The text file has been created with one value on each line. Due to the potential for the sum of the numbers to be very large, you should use a long integer in your calculation to find the average.

2. The number of integers in the file is unknown. You must read the text file until the EOF marker is encountered.

3. Your program must find the average, standard deviation, and mode of the list of numbers. The mode is defined as the value(s) present with the highest frequency. Calculating the standard deviation consists of the following steps:

   a. Find the average of the list of numbers.
   b. Determine the difference of each number from the average, and square each difference. Sum all the differences.
   c. Divide this sum by (the number of values - 1).
   d. Take the square root of the above division problem from step c.

   Example, given this list of numbers: 7 4 5 9 10

   a. The average = 7
   b. Sum of square of differences:

$$\begin{array}{ccccccccccc} (7-7)^2 & + & (4-7)^2 & + & (5-7)^2 & + & (9-7)^2 & + & (10-7)^2 & & \\ 0 & + & 9 & + & 4 & + & 4 & + & 9 & = & 26 \end{array}$$

   c. $\frac{26}{(5-1)} = 6.50$

   d. $\sqrt{6.50} = 2.55$

4. For a normal distribution, 68.3% of the data will lie within one standard deviation of the average, while 95.4% will lie within two standard deviations.

Assignment:

1. Your program should print out the average, standard deviation, and mode of the data in *numbers.txt.* Format the real numbers to print with 2 decimal places.

2. Your program must utilize proper modular design and parameter passing.

3. Turn in your source code and run output.

LAB EXERCISE

Compact

Background:

A common task in array processing is to traverse a list and eliminate an undesired value. You will be provided with a text file named *compact.txt*, which contains non-negative (≥0) integers in random order. A text file of integers is provided. The number of integers in the file is not given, but it is no more than 100.

Assignment:

1. Write a program that reads a text file (*compact.txt*) and stores the integers in an array. Your instructor will provide this text file.

2. Write a method `compact` that removes all zeroes from the array, leaving the order of the other elements unchanged. All local variables within this function must be scalar. In other words, you may not use a second array to solve the problem.

3. Do not solve the problem by printing out only the non-zero values in the array. The `compact` method must remove all zeroes from the array.

Instructions:

1. Print out the list both before and after removing the zeros. For example:

   Before: 0, 9, 7, 0, 0, 23, 4, 0

   After: 9, 7, 23, 4

2. Your program must use proper modular design and parameter passing.

EXAMPLE PROGRAM • ARRAYS AS PARAMETERS

```
public class ArrayOps
{
  public ArrayOps() { }

  // Copy source to target
  public void copy (int[] source, int[] target)
  {
    for (int count=0; count < source.length; count++)
      target[ count ] = source[ count ];
  }

  public void printList (int[] list)
  /* list is a reference parameter.  list is the same array as
    array data in the main method */
  {
    for (int index = 0; index < list.length; index++)
      System.out.print( list[index] + "   ");

    System.out.println();
    System.out.println();
  }

  public void squareList (int[] list)
  /* Array list is a local alias for array data in the main method.  Any
    reference to local list is a reference to array data in function main.  */
  {
    for (int index = 0; index < list.length; index++)
      list[index] = list[index] * list[index];
  }

  public void rotateList (int[] list)
  /*  This function is working with a local copy of the array passed
      as an argument.  Changes to local array list will have no effect
      on the array data in the calling method.  This function will shift each
      value one cell to the right.  The value in list[list.length-1] will be
      moved to list[0].  Before the function is completed, printList will
      be called.  The point of this function is to illustrate an array as
      a value parameter.  */
  {
    int temp = list[list.length-1];

    int[] listCopy = new int[ list.length ];

    copy(list, listCopy);

    for (int loop = listCopy.length-1; loop > 0; loop--)
      listCopy[loop] = listCopy[loop-1];
    listCopy[0] = temp;

    System.out.println("Inside of rotateList:  ");
    printList (listCopy);
```

```
  }

  public static void main (String[] args)
  {
    final int MAX = 6;

    ArrayOps arrayOps = new ArrayOps();

    int[] data = new int[MAX];

    for (int loop = 0; loop < MAX; loop++)
      data[loop] = loop;   // initialize array

    System.out.println("Array initialized:  ");

    arrayOps.printList(data);   // print array in ascending order
    arrayOps.squareList (data);
    System.out.println("Array after call of squareList:  ");
    arrayOps.printList (data);
    arrayOps.rotateList (data);
    System.out.println("Array after call of rotateList:  ");
    arrayOps.printList (data);  // print list again
  }
}
```
